1.

Suppose that you have trained a logistic regression classifier, and it outputs on a new example x a prediction  $h_{\theta}(x)$  = 0.7. This means (check all that apply):

Our estimate for  $P(y = 1|x; \theta)$  is 0.7.

Our estimate for  $P(y = 0|x; \theta)$  is 0.3.

Our estimate for  $P(y = 1|x; \theta)$  is 0.3.

Our estimate for  $P(y = 0|x; \theta)$  is 0.7.

2.

Suppose you have the following training set, and fit a logistic regression Logistic Regression  $g(\theta_0 + \theta_1 x_1 + \theta_2 x_2)$ .

Quiz, 5 questions

$x_1$	<i>x</i> <sub>2</sub>	у
1	0.5	0
1	1.5	0
2	1	1
3	1	0

Which of the following are true? Check all that apply.

Adding polynomial features (e.g., instead using  $h_{\theta}(x) = g(\theta_0 + \theta_1 x_1 + \theta_2 x_2 + \theta_3 x_1^2 + \theta_4 x_1 x_2 + \theta_5 x_2^2) \text{ ) could increase how well we can fit the training data.}$ 

At the optimal value of  $\theta$  (e.g., found by fminunc), we will have  $J(\theta) \geq 0$ .

Adding polynomial features (e.g., instead using  $h_{\theta}(x) = g(\theta_0 + \theta_1 x_1 + \theta_2 x_2 + \theta_3 x_1^2 + \theta_4 x_1 x_2 + \theta_5 x_2^2) \text{ ) would increase } J(\theta) \text{ because we are now summing over more terms.}$ 

If we train gradient descent for enough iterations, for some examples  $x^{(i)}$  in the training set it is possible to obtain  $h_{\theta}(x^{(i)}) > 1$ .

3.

For logistic regression, the gradient is given by

Quiz, 5 questions

**Logistic Regression**  $\sum_{m=1}^{m} (h_{\theta}(x^{(i)}) - y^{(i)}) x_{j}^{(i)}$ . Which of these is a correct gradient

descent update for logistic regression with a learning rate of  $\alpha$ ? Check all that apply.

- $\theta_j := heta_j lpha \, rac{1}{m} \, \sum_{i=1}^m \, ig( heta^T x y^{(i)} ig) x_j^{(i)}$  (simultaneously update for all
- $\theta := \theta \alpha \, \frac{1}{m} \, \sum_{i=1}^{m} \left( \frac{1}{1 + e^{-\theta^T x^{(i)}}} y^{(i)} \right) x^{(i)}.$
- $\theta := \theta \alpha \frac{1}{m} \sum_{i=1}^{m} (\theta^{T} x y^{(i)}) x^{(i)}.$
- $\theta := \theta \alpha \frac{1}{m} \sum_{i=1}^{m} (h_{\theta}(x^{(i)}) y^{(i)}) x^{(i)}.$

4.

Which of the following statements are true? Check all that apply.

- The cost function  $J(\theta)$  for logistic regression trained with  $m \ge 1$ examples is always greater than or equal to zero.
- The one-vs-all technique allows you to use logistic regression for problems in which each  $y^{(i)}$  comes from a fixed, discrete set of values.
- Since we train one classifier when there are two classes, we train two classifiers when there are three classes (and we do one-vs-all classification).
- For logistic regression, sometimes gradient descent will converge to a local minimum (and fail to find the global minimum). This is the reason we prefer more advanced optimization algorithms such as fminunc (conjugate gradient/BFGS/L-BFGS/etc).

5.

Suppose you train a logistic classifier  $h_{\theta}(x) = g(\theta_0 + \theta_1 x_1 + \theta_2 x_2)$ . Suppose  $\theta_0 = -6, \theta_1 = 1, \theta_2 = 0$ . Which of the following figures represents the decision boundary found by your classifier?
